# URBAN MAPPING AND CHANGE DETECTION

Sebastian van der Linden  
with contributions from Akpona Okujeni

Humboldt-Universität zu Berlin, Germany

# Introduction

# Introduction – The urban millennium

Source: United Nations, 2014

Johannesburg

Istanbul

New York

Moscow

Tehran

Oslo

Urban areas mark an extreme in terms of human domestication of nature.

Urban environments are very diverse in terms of size, shape, material composition and fragmentation.

Manaus

Tokyo

Dubai

Berlin-Brandenburg area in Global Urban  
Footprint TerraSAR-X product of DLR

Urban environments are not fully composed of built-up  
structures or impervious areas.  
Different sensors contribute differently to mapping  
urban extent and urban composition.

# Projection Filtered

South-east Asia in multi-temporal nighttime lights composite.

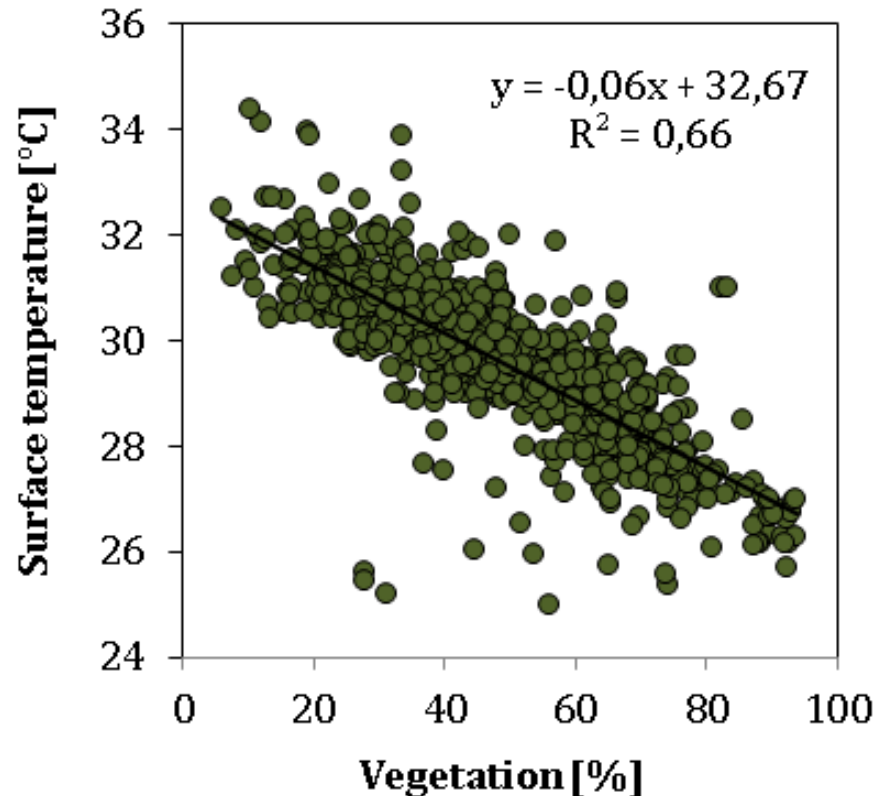

Urban environments are characterized by high temporal dynamics.

Mapping urban growth is one of the key applications for urban remote sensing.

1992 2001 2009

Source: Small & Elvidge, 2012

Urban material composition influences the micro climate and other environmental variables.

Source: Wikimedia Commons

A detailed description of urban composition (ideally fractions!) is needed for many environmental analysis. Remote sensing contributes to urban planning, micro climatology, hydrology, hazard or habitat modelling, etc.

Temp  
°C

# Introduction (summary)

With more than half of the world's population living in cities and rapid urbanization rates, remote sensing plays a pivotal role in monitoring urban environments.

Especially in less developed countries and for fast growing urban agglomerations remote sensing is often the only reliable source of spatial information.

Most urban environmental models use remotely sensed maps as input.

Remote sensing analyses usually focus on

- mapping urban extent and growth
- mapping urban composition

# Characteristics and challenges of urban land cover and urban remote sensing

# Urban land cover

Urban land cover is characterized by great diversity of materials.

*Source: Google Earth*

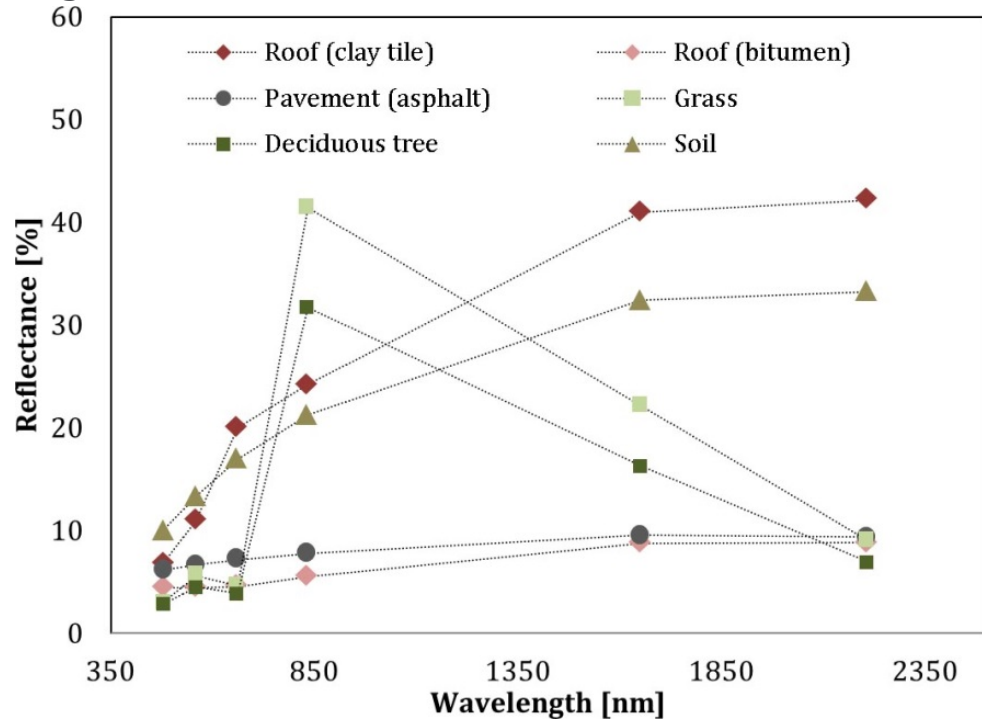

# Urban land cover

Urban land cover is characterized by high intra-class variation and often spectral ambiguity between classes.

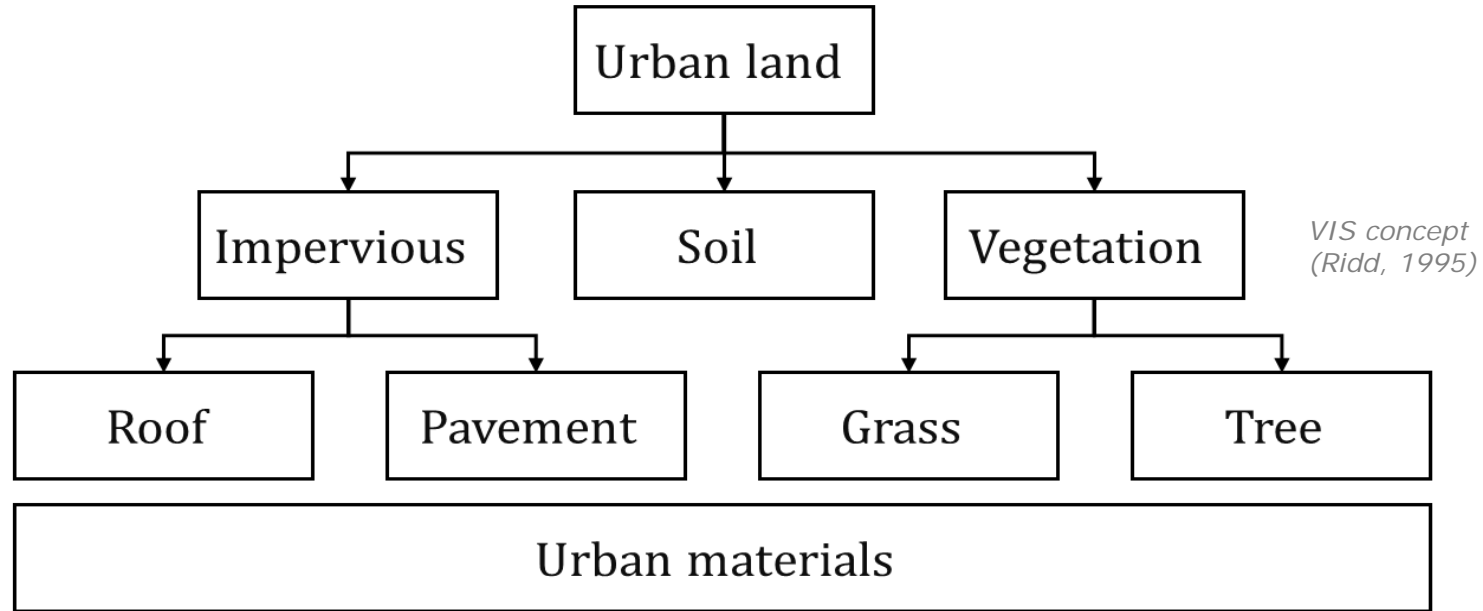

Landsat ETM+ (30 m; 6 spectral bands)

# Urban land cover

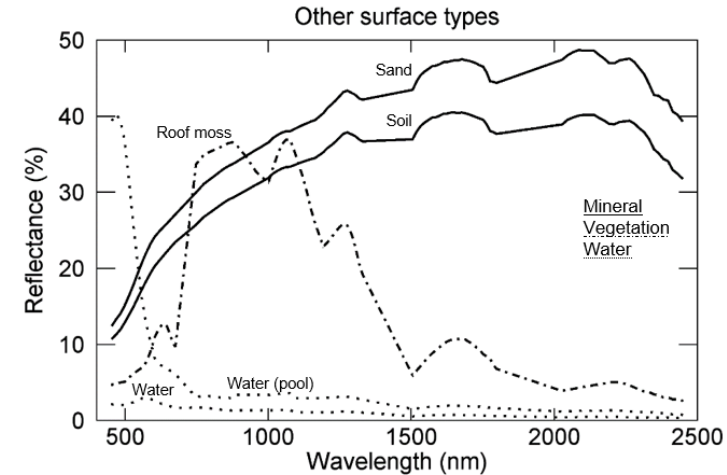

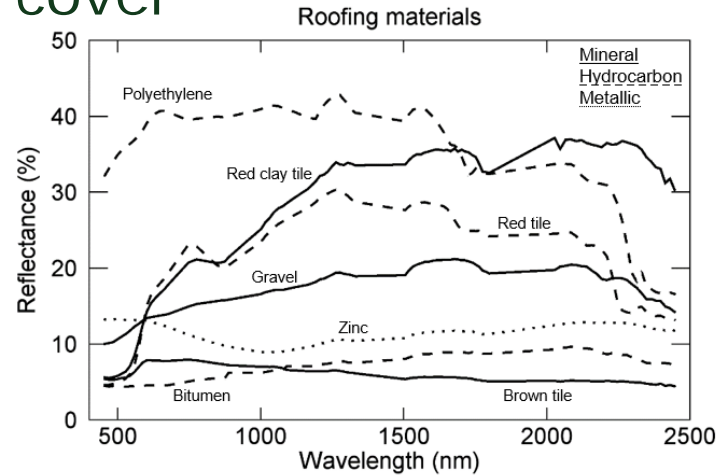

Urban land cover classes can be hierarchically organized down to the material level.

# Urban land cover

High spectral diversity of construction materials and natural surface types.

# Urban land cover

30x30 km footprint of Berlin,  
Germany, as seen by

UL: Landsat 8 (swIR, nIR, red)

UR: Landsat 8 thermal

LL: Sentinel-1A

LR: vis. nightlights (ISS photo).

Each observation provides  
complementary information,  
but is also subject to non-  
uniqueness.

# Urban land cover

Polarimetric representation of Berlin area and three subsets using TerraSAR-X StripMap data in the Pauli color coding scheme (R: HH-VV, G: HV, B: HH+VV).

Mirror-like reflectors appear dark (streets, sport fields, water). Vegetation is greenish with HV dominating. Strong backscatter structure appear bright with the actual color also depending on object size, geometric arrangement and orientation.

*Source: Small et al., in press*

# Urban land cover

Berlin area thermal emissions in July and September during day (middle) and night (bottom). Landsat 7 for comparison (top).

Water bodies show low values at day and highest at night. Urban forests are always in mid-ranges. Street canyons and large buildings store energy longer and emit even at nighttime.

Map of Karachi, Pakistan

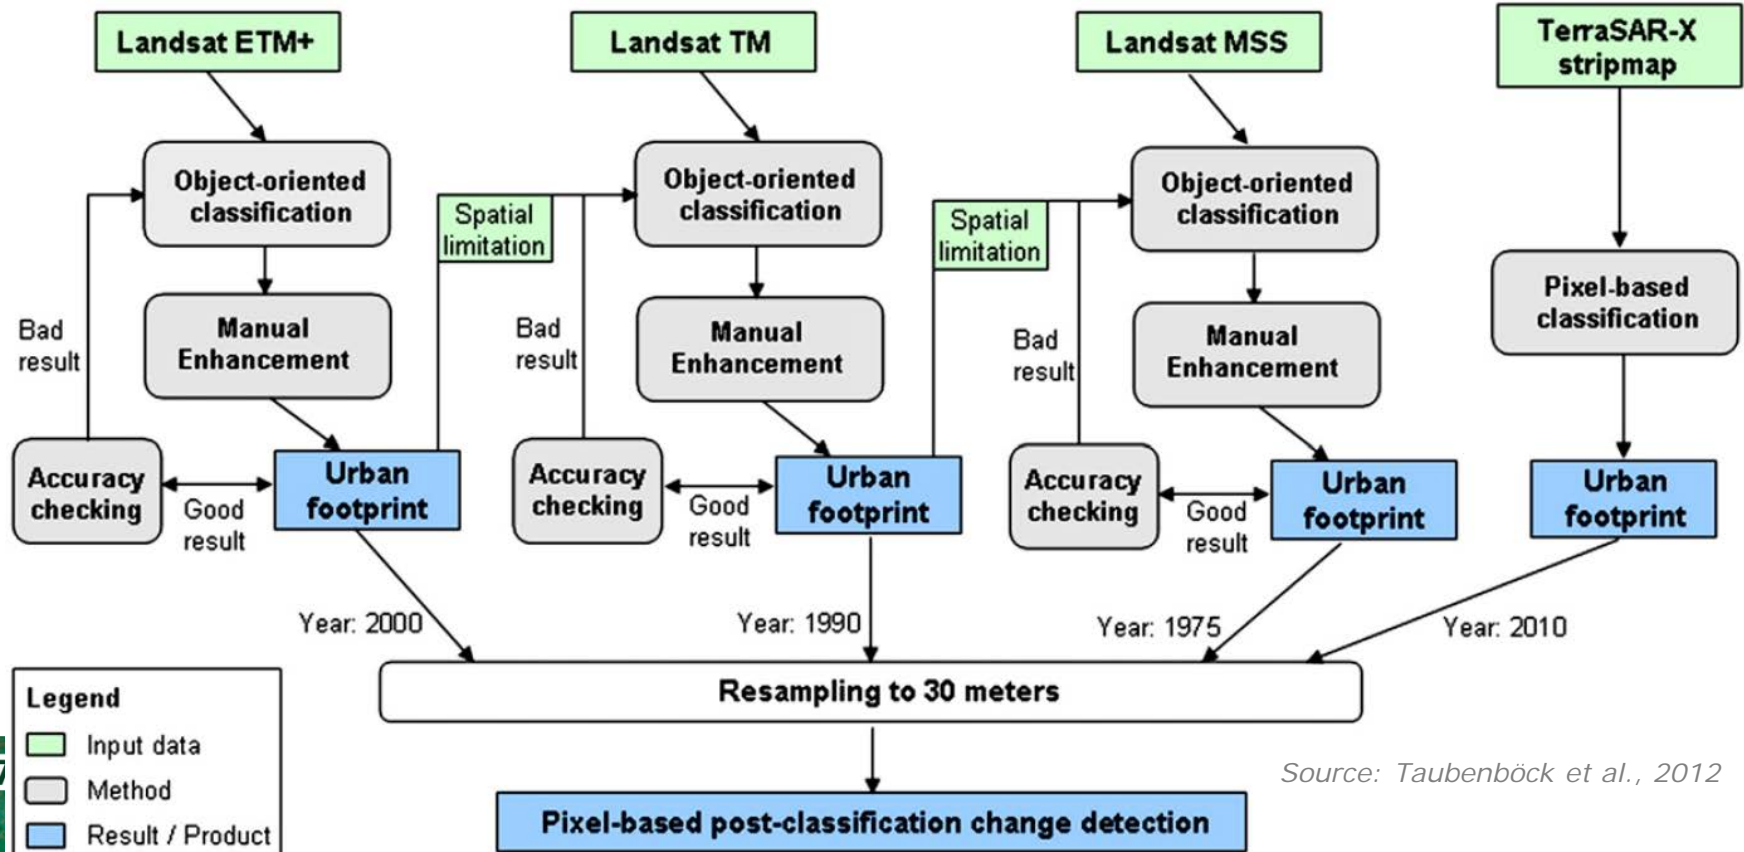

Source: Taubenböck et al., 2012

# Mapping urban growth from optical and SAR data

Landsat and TerraSAR data are classified with different approaches.

# Mapping urban growth from spectral and SAR data

Griffiths et al. (2010) monitor the growth of Dhaka, Bangladesh, for 1990, 2000 and 2006 based on Landsat TM/ETM+ and ERS-1/ASAR data.

By fusing the multispectral optical and the SAR data they can map urban extent reliably in this heavily monsoon and flooding influenced area of rapid urbanization.

Both sensor types contribute to the high overall accuracy.

Source: Griffiths et al., 2010

## *2006 – Results of feature selection – 2 classes*

#1	ETM+(27.01.06) b6	72.3
#2	SAR (02.12.07) HH	90.1
#3	ETM+(27.01.06) b4	92.1
#4	SAR (31.10.07) HH	93.0

# Mapping urban composition

# Mapping urban composition from spectral data

Ridd (1995) assumes, every urban pixel is composed of impervious surface, vegetation or soil.

Ridd's V-I-S concept is based on a thematical framework. It is not based on the spectral characteristics of urban areas.

# Mapping urban composition from spectral data

Small (2005) analyses more than 24 urban areas and concludes that the spectral properties working with Landsat ETM+ always relate to the degree of brightness and the portion of vegetation. This results in a mixing triangle in the first Two PC components.

# Species mapping in urban areas

Urban tree species mapping using 3.7 m AVIRIS plus LiDAR data, later on used for LAI and carbon mapping (Alonzo et al., 2014)

“We find that the addition of lidar data are critical for mapping species with small crowns and those with unique crown forms.”

Source: Alonzo et al., 2014

# Mapping class fractions from spectral data

Given the high number of mixed pixels in spaceborne data, quantitative mapping appears more useful than traditional classification to describe urban composition.

Concepts for quantitative mapping most often assume a linearly mixed spectrum, which can be decomposed into “pure” components, e.g. by linear spectral mixture analysis.

# Mapping class fractions from spectral data

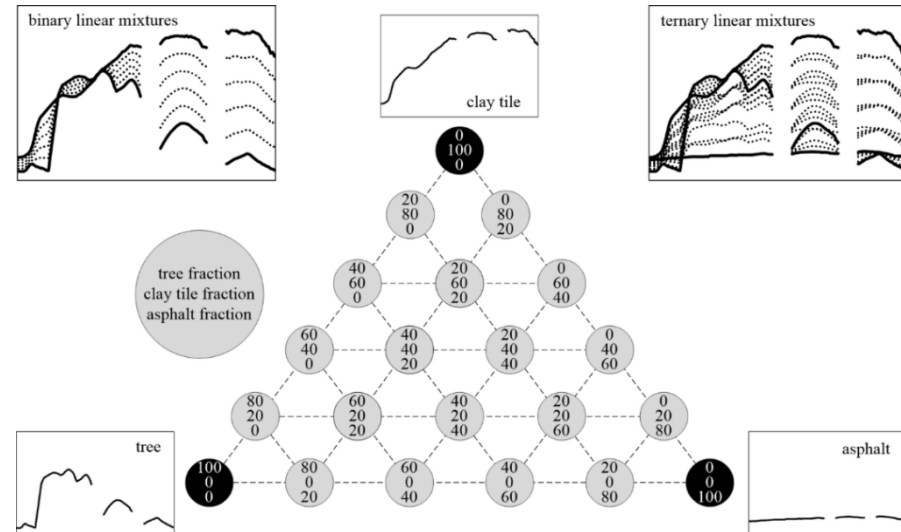

SVRsynthmix (Okujeni, van der Linden et al., 2013, 2015, 2017)

Machine learning algorithms (e.g. for classification and regression) were shown to produce robust and accurate results with spectral data and overcome statistical approaches, like spectral mixture analysis.

Regression requires fractional training data, which is usually not available.

This challenge is coped with by creating synthetic mixtures with known labels, which serve as training data for the supervised mapping approach.

Linear mixing is assumed and binary ternary mixtures of pure components are performed.

Source: Okujeni et al., 2017

# Mapping class fractions from spectral data

tree fraction  
clay tile fraction  
asphalt fraction

Large spectral libraries result in an excessive amount of samples.

E.g. 75 spectra result in ~400.000 binary and ternary mixed spectra

Source: Okujeni et al., 2017

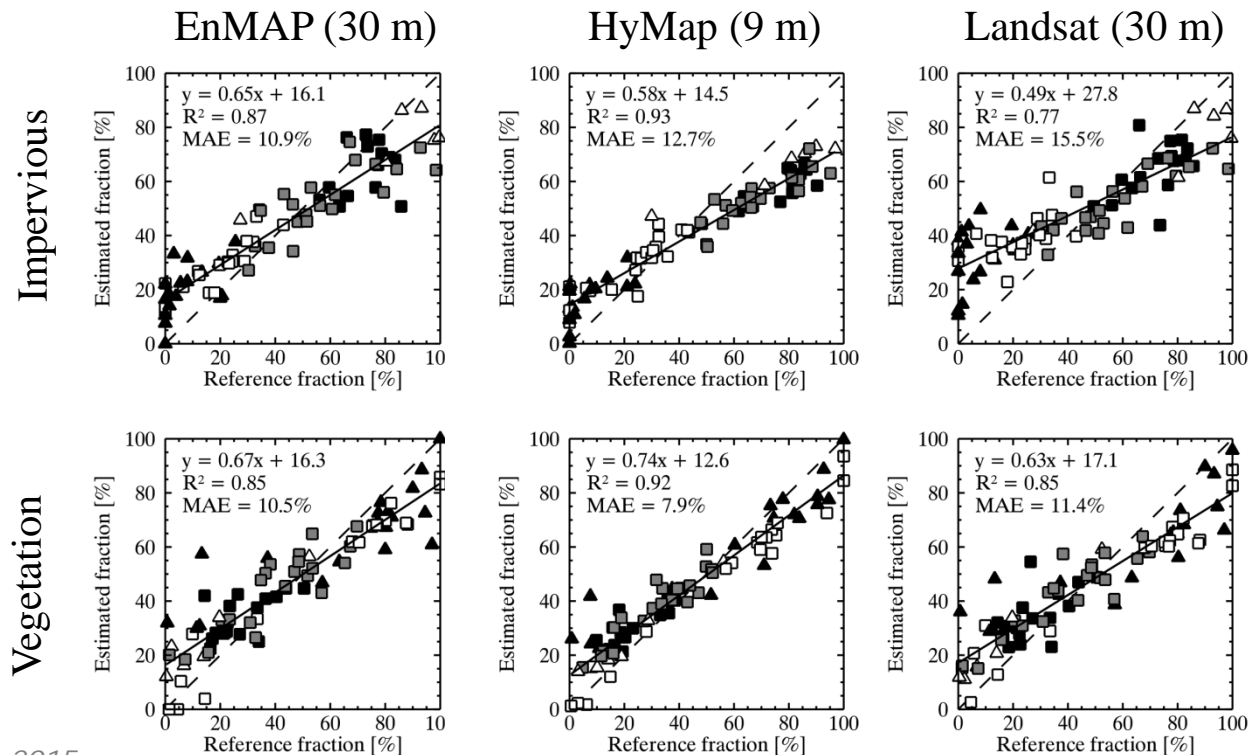

# Mapping class fractions from spectral data

All VIS components can be modelled at high accuracy using SVR with synthetic mixtures.

The decrease in accuracy from 9 m to 30 m is relatively low.

EnMAP data leads to slightly better results than Landsat data.

Results for soils (not shown) are comparable.

urban area

Source: Okujeni et al., 2015

# Mapping class fractions from spectral data

The SVR with synthetic mixtures allows extending the VIS framework for two vegetation and impervious types, although a clear decrease in accuracies can be observed for tree cover.

This time, the accuracy from EnMAP is clearly better than for Landsat.
